# Multi-armed Bandits

- The agent interacts with the environment for  $T$  rounds.
- In each round  $t$ , the agent chooses an action  $a_t \in [K]$
- Standard reward  $r_t$  is generated independently from inlier distribution.
- After contamination, the agent observes contaminated reward  $X_t$ .

# Robustness:

## Two Classes of Heavy-tailed Reward Distributions

### Definition (Finite $k$ -th raw moment)

A distribution over  $\mathbb{R}$  is said to have a finite  $k$ -th raw moment if it is within

$$\mathcal{P}_k = \left\{ P : \mathbb{E}_{X \sim P} \left[ |X|^k \right] \leq 1 \right\}, \quad k \geq 2,$$

where  $k$  is considered fixed but arbitrary.

### Definition (Finite $k$ -th central moment)

A distribution over  $\mathbb{R}$  is said to have a finite  $k$ -th central moment if it is within

$$\mathcal{P}_k^c = \left\{ P : \mathbb{E}_{X \sim P} \left[ |X - \mu|^k \right] \leq 1 \right\}, \quad k \geq 2,$$

where  $\mu := \mathbb{E}_{X \sim P}[X] \in [-D, D]$  and  $D \geq 1$ .

# Robustness:

## Huber Model

### Definition (Heavy-tailed MABs with Huber contamination)

Given the corruption level  $\alpha \in [0, 1/2)$ . For each round  $t \in [T]$ , the observed reward  $x_t$  for action  $a_t$ , is sampled independently from the true distribution  $P_{a_t} \in \mathcal{P}_k$  (or  $P_{a_t} \in \mathcal{P}_k^c$ ) with probability  $1 - \alpha$ ; otherwise is sampled from some arbitrary and unknown contamination distribution  $G_{a_t} \in \mathcal{G}$ .

## Definition (Differential Privacy for MABs)

For any  $\epsilon > 0$ , a learning algorithm  $\mathcal{M} : \mathbb{R}^T \rightarrow [K]^T$  is  $\epsilon$ -DP if for all sequences  $\mathcal{D}_T, \mathcal{D}'_T \in \mathbb{R}^T$  differing only in a single element and for all events  $E \subset [K]^T$ , we have

$$\mathbb{P}[\mathcal{M}(\mathcal{D}_T) \in E] \leq e^\epsilon \cdot \mathbb{P}[\mathcal{M}(\mathcal{D}'_T) \in E].$$

# Regrets

- $\mu_a$ : the mean of the inlier distribution of arm  $a \in [K]$ ;
- $\mu^* = \max_{a \in [K]} \mu_a$ ;
- $\Pi^\epsilon$ : the set of all  $\epsilon$ -DP MAB algorithms;
- $\mathcal{E}_{\alpha,k}$ : the set of all instances of heavy-tailed MABs (with parameter  $k$ ) with Huber contamination (of level  $\alpha$ ).

## Definition (Clean Regret)

Fix an algorithm  $\pi \in \Pi^\epsilon$  and an instance  $\nu \in \mathcal{E}_{\alpha,k}$ . Then, the clean regret of  $\pi$  under  $\nu$  is given by  $\mathcal{R}_T(\pi, \nu) := \mathbb{E}_{\pi, \nu} [T\mu^* - \sum_{t=1}^T \mu_{a_t}]$ .

To capture the intrinsic difficulty of the private and robust MAB problem, we are also interested in its minimax regret.

## Definition (Minimax Regret)

The minimax regret of our private and robust MAB problem is defined as  $\mathcal{R}_{\epsilon, \alpha, k}^{\text{minimax}} := \inf_{\pi \in \Pi^\epsilon} \sup_{\nu \in \mathcal{E}_{\alpha, k}} \mathbb{E}_{\pi, \nu} [T\mu^* - \sum_{t=1}^T \mu_{a_t}]$ .

## Theorem

*Consider a private and robust MAB problem where inlier distributions have finite  $k$ -th raw (or central) moments ( $k \geq 2$ ). Then, its minimax regret satisfies*

$$\mathcal{R}_{\epsilon, \alpha, k}^{\text{minimax}} = \Omega \left( \sqrt{KT} + (K/\epsilon)^{1-\frac{1}{k}} T^{\frac{1}{k}} + T\alpha^{1-\frac{1}{k}} \right).$$

# A Meta Algorithm

---

**Algorithm 1** Private and Robust Arm Elimination

---

- 1: **Input:** Number of arms  $K$ , time horizon  $T$ , privacy budget  $\epsilon$ , Huber parameter  $\alpha \in (0, 1/2)$ , error probability  $\delta \in (0, 1]$ , inlier distribution parameters i.e.,  $k$  and optional  $D$ .
- 2: **Initialize:**  $\tau = 0$ , active set of arms  $\mathcal{S} = \{1, \dots, K\}$ .
- 3: **for** batch  $\tau = 1, 2, \dots$  **do**
- 4:   Set batch size  $B_\tau = 2^\tau$ .
- 5:   **if**  $B_\tau < \mathcal{T}$  **then**
- 6:     Randomly select an action  $a \in [K]$ .
- 7:     Play action  $a$  for  $B_\tau$  times.
- 8:   **else**
- 9:     **for** each active arm  $a \in \mathcal{S}$  **do**
- 10:      **for**  $i$  from 1 to  $B_\tau$  **do**
- 11:       Pull arm  $a$ , observe contaminated reward  $x_i^a$ .
- 12:       If total number of pulls reaches  $T$ , **exit**.
- 13:      **end for**
- 14:      Set truncation threshold  $M_\tau$ .
- 15:      Set additional parameters  $\Phi$ .
- 16:      Compute estimate  $\tilde{\mu}_a = \text{PRM}(\{x_i^a\}_{i=1}^{B_\tau}, M_\tau, \Phi)$ .
- 17:     **end for**
- 18:     Set confidence radius  $\beta_\tau$ .
- 19:     Let  $\tilde{\mu}_{\max} = \max_{a \in \mathcal{S}} \tilde{\mu}_a$ .
- 20:     Remove all arms  $a$  from  $\mathcal{S}$  s.t.  $\tilde{\mu}_{\max} - \tilde{\mu}_a > 2\beta_\tau$ .
- 21:   **end if**
- 22: **end for**

# Finite Raw Moment Case

---

**Algorithm 2** PRM for the finite raw moment case

---

- 1: **Input:** A collection of data  $\{x_i\}_{i=1}^n$ , truncation parameter  $M$ , additional parameters  $\Phi = \{\epsilon\}$ .
  - 2: **for**  $i = 1, 2, \dots, n$  **do**
  - 3:   Truncate data  $\bar{x}_i = x_i \cdot \mathbb{1}_{\{|x_i| \leq M\}}$ .
  - 4: **end for**
  - 5: Return private estimate  $\tilde{\mu} = \frac{\sum_{i=1}^n \bar{x}_i}{n} + \text{Lap}\left(\frac{2M}{n\epsilon}\right)$ .
- 

## Theorem (Performance Guarantees)

Consider a private and robust MAB with inlier distributions satisfying Definition 1 and  $0 < \alpha \leq \alpha_1 \in (0, 1/2)$ . Let Algorithm 1 be instantiated with Algorithm 2. Set  $\mathcal{T} = \Omega\left(\frac{\log(1/\delta)}{\alpha_1}\right)$  and  $\delta = 1/T$ . Then Algorithm 1 is  $\epsilon$ -DP with its regret upper bound

$$\mathcal{R}_T = O\left(\sqrt{KT \log T} + \left(\frac{K \log T}{\epsilon}\right)^{\frac{k-1}{k}} T^{\frac{1}{k}} + T \alpha_1^{1-\frac{1}{k}} + \frac{K \log T}{\alpha_1}\right).$$

# Finite Central Moment Case

---

## Algorithm 3 PRM for the finite central moment case

---

- 1: **Input:** A collection of data  $\{x_i\}_{i=1}^{2n}$ , truncation parameter  $M$ , additional parameters  $\Phi = \{\epsilon, D, r\}$ ,  $r \in \mathbb{R}$ .
  - 2: // **First step: initial estimate**
  - 3:  $B_j = [j, j + r)$ ,  $j \in \mathcal{J} = \{-D, -D + r, \dots, D - r\}$ .
  - 4: Compute private histogram using the first fold of data:  $\tilde{p}_j = \frac{\sum_{i=1}^n \mathbb{1}_{\{X_i \in B_j\}}}{n} + \text{Lap}\left(\frac{2}{n\epsilon}\right)$ .
  - 5: Get the initial estimate  $J = \arg \max_{j \in \mathcal{J}} \tilde{p}_j$ .
  - 6: // **Second step: final estimate**
  - 7: Get final estimator using the second fold of data:  $\tilde{\mu} = J + \frac{1}{n} \sum_{i=n+1}^{2n} (X_i - J) \mathbb{1}_{\{|X_i - J| \leq M\}} + \text{Lap}\left(\frac{2M}{n\epsilon}\right)$ .
-

# Finite Central Moment Case

## Theorem (Performance Guarantees, $\alpha = 0$ )

Let Algorithm 1 be instantiated with Algorithm 3. Set  $\mathcal{T} = \Omega\left(\frac{\log(D/\delta)}{\epsilon}\right)$  and  $\delta = 1/T$ . Then, Algorithm 1 is  $\epsilon$ -DP with its regret upper bound

$$\mathcal{R}_T = O\left(\sqrt{KT \log T} + (K \log T / \epsilon)^{\frac{k-1}{k}} T^{\frac{1}{k}} + \gamma\right),$$

where  $\gamma := O(KD \log(DT) / \epsilon)$ .

## Theorem (Performance Guarantees, $\alpha > 0$ )

For  $\alpha \leq \alpha_1 \in (0, 0.133)$ , let Algorithm 1 be instantiated with Algorithm 3. Set  $\delta = 1/T$ , then Algorithm 1 is  $\epsilon$ -DP with its regret upper bound

$$\mathcal{R}_T = O\left(\sqrt{KT \log T} + (K \log T / \epsilon)^{\frac{k-1}{k}} T^{\frac{1}{k}} + T \alpha_1^{1-\frac{1}{k}} + \hat{\gamma}\right),$$

where  $\hat{\gamma} := O\left(\frac{DK \log T}{\alpha_1^2} + \frac{\iota DK \log T}{\epsilon} + \frac{DK \log(DT)}{\epsilon}\right)$  and  $\iota = \frac{1-\alpha}{0.249-\alpha}$ .
