# The Interior Point Method

## Problem

We focus on solving the following NLP (1):

$$\begin{aligned} \min_{x \in \mathbb{R}^n} \quad & f(x) \\ \text{s.t.} \quad & h(x) = 0 \\ & x \geq 0 \end{aligned} \tag{1}$$

where the functions  $f: \mathbb{R}^n \rightarrow \mathbb{R}$  and  $h: \mathbb{R}^n \rightarrow \mathbb{R}^m$  are all assumed to be twice continuously differentiable.

# The Interior Point Method

## The Classic IPM

By introducing a decreasing sequence of parameters  $\mu$  converging to zero, the perturbed *Karush-Kuhn-Tucker* (KKT) conditions can be represented as:

$$\begin{aligned} \nabla f(x) + \lambda^\top \nabla h(x) - z &= 0 & h(x) &= 0 \\ \text{diag}(z)\text{diag}(x)e &= \mu e & x, z &\geq 0 \end{aligned} \quad (2)$$

A one-step Newton's method is employed to solve such a system, aiming to solve systems of linear equations (3).

$$\underbrace{\begin{bmatrix} \nabla^2 f(x) + \lambda^\top \nabla^2 h(x) & \nabla h^\top(x) & -I \\ \nabla h(x) & & \\ \text{diag}(z) & & \text{diag}(x) \end{bmatrix}}_J \begin{bmatrix} \Delta x \\ \Delta \lambda \\ \Delta z \end{bmatrix} = -F(x, \lambda, z) \quad (3)$$

The IPM commences with an initial solution  $(x^0, \lambda^0, z^0)$  such that  $x^0, z^0 > 0$ . At iteration  $k$ , the linear system (3) defined by the current iterate  $(x^k, \lambda^k, z^k)$  is solved.

# The Interior Point Method

## The Classic IPM

---

### Algorithm 1 The classic IPM

---

**Inputs:** An initial solution  $(x^0, \lambda^0, z^0)$ ,  $\sigma \in (0, 1)$ ,  $k \leftarrow 0$

**Outputs:** The optimal solution  $(x^*, \lambda^*, z^*)$

- 1: **while** not converged **do**
  - 2:   Update  $\mu^k$
  - 3:   Solve the system  $J^k [(\Delta x^k)^\top, (\Delta \lambda^k)^\top, (\Delta z^k)^\top]^\top = -F^k$
  - 4:   Choose  $\alpha^k$  via a line-search filter method
  - 5:    $(x^{k+1}, \lambda^{k+1}, z^{k+1}) \leftarrow (x^k, \lambda^k, z^k) + \alpha^k (\Delta x^k, \Delta \lambda^k, \Delta z^k)$
  - 6:    $k \leftarrow k + 1$
  - 7: **end while**
- 

- Solving linear systems is the main computational bottleneck.
- IPM is difficult to be warm-started.

*Can we leverage L2O techniques to expedite IPMs for NLPs?*

# The Interior Point Method

## Approximating Solutions to Linear Systems

To avoid high computational costs, the least squares problem (4) is employed to obtain the approximate solution of the IPM linear system.

$$\min_y \frac{1}{2} \left\| J^k y + F^k \right\|^2 \quad (4)$$

This perspective is similar to the inexact IPM<sup>1</sup>.

### Assumption 1

At iteration  $k$ , we could identify some  $y^k$  such that

$$\left\| J^k y^k + F^k \right\| \leq \eta \left[ (z^k)^\top x^k \right] / n \quad (5)$$

$$\|y^k\| \leq (1 + \sigma + \eta) \|F_0(x^k, \lambda^k, z^k)\|. \quad (6)$$

where  $\eta \in (0, 1)$  and  $F_0(x^k, \lambda^k, z^k)$  denotes  $F(x^k, \lambda^k, z^k)$  with  $\mu = 0$ .

<sup>1</sup>Stefania Bellavia. "Inexact interior-point method". In: *Journal of Optimization Theory and Applications* 96 (1998), pp. 109–121.

# The Interior Point Method

## Approximating Solutions to Linear Systems

To satisfy Assumption 1, the approximate solution  $y^k$  has to be **bounded** and **accurate enough**, regardless of whether  $J^k$  is invertible.

### Proposition 1

If  $(x^k, \lambda^k, z^k)$  is generated such that Assumption 1 is satisfied, let  $(x^*, \lambda^*, z^*)$  denote a limit point of the sequence  $\{(x^k, \lambda^k, z^k)\}$ , then  $\{(x^k, \lambda^k, z^k)\}$  converges to  $(x^*, \lambda^*, z^*)$  and  $F_0(x^*, \lambda^*, z^*) = 0$ .

# The IPM-LSTM Approach

## Architecture

LSTM networks are considered suitable for solving the least squares problem due to the resemblance between LSTM recurrent calculations and iterative algorithms.

$$y_t := \text{LSTM}_\theta \left( \left[ y_{t-1}, (J^k)^\top (J^k y_{t-1} + F^k) \right] \right). \quad (7)$$

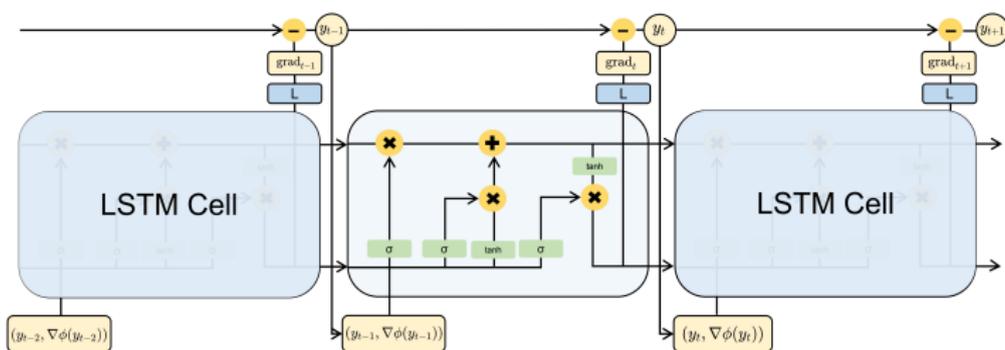

Figure 1: The LSTM architecture for solving the least squares problem.

# The IPM-LSTM Approach

## Model Training

Base on the least squares problem, we propose a new self-supervised loss function:

$$\min_{\theta} \frac{1}{|\mathcal{M}|} \sum_{M \in \mathcal{M}} \left( \frac{1}{K} \sum_{k=1}^K \frac{1}{T} \sum_{t=1}^T \frac{1}{2} \left\| J^k y_t^k(\theta) + F^k \right\|^2 \right)_M,$$

where the subscript  $M$  indicates that the corresponding term is associated with instance  $M$ . *Truncated backpropagation through time* is employed to mitigate memory issues.

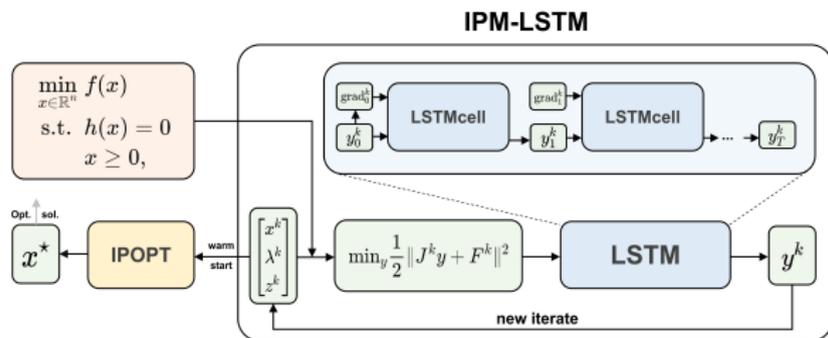

Figure 2: An illustration of the IPM-LSTM approach.

## Experimental Settings

### Datasets:

The dataset used in our work includes randomly generated benchmarks<sup>234</sup> as well as real-world instances from Globallib. These benchmarks encompass **convex QPs**, **convex QCQPs**, **nonconvex QPs**, and **simple non-convex programs**.

### Baselines:

- Traditional optimizer: OSQP, IPOPT.
- L2O algorithms : NN, DC3, DeepLDE, PDL, LOOP-LC, H-Proj.

# Conclusions

Our work can be summarized as follows:

- Approximating Solutions to Linear Systems via LSTM.
- A new self-supervised loss function.
- A new learning-based method based on IPM that can simultaneously keep feasibility and optimality.
- Two-Stage Framework.
- Better performance in end-to-end solutions and warm-starting IPOPT.
